## 1 Toy model: 0d GLSM

#### 1.1 Setup

We start with a 0d GLSM toy model, i.e. we consider the source manifold  $\Sigma = \{pt\}$  to be an abstract point and the target manifold to be

$$X = \mathbb{CP}^{N-1} \times \mathbb{CP}^{N-1}$$

The space of fields is then simply given by points on the target manifold X, namely

$$\mathcal{F} = \mathbb{CP}^{N-1} \times \mathbb{CP}^{N-1} \tag{1}$$

As the action of the model we consider

$$S(z,w) = \beta |\langle \bar{z},w\rangle|^2 = \beta \sum_{j,k=0}^{N-1} \bar{z}_j z_k \bar{w}_j w_k \tag{2} \qquad \text{ {eq:toy\_S}}$$

where  $z, w \in \mathbb{C}^N$  subject to the condition

$$|z|^2 = \sum_j |z_j|^2 = 1$$
 ,  $|w|^2 = \sum_k |w_k|^2 = 1$  (3) {eq:toy\_constr}

The action enjoys a  $U(1) \times U(1)$  gauge freedom (which here is simply a global  $U(1) \times U(1)$  symmetry, acting as

$$e^{i\theta} \times e^{i\varphi} \colon (z, w) \mapsto (e^{i\theta}z, e^{i\varphi}w)$$
 (4)

Under the assumption of the condition (3), the action (2) does define a function on  $\mathbb{CP}^{N-1} \times \mathbb{CP}^{N-1}$ .

The path integral of the model is defined by

$$Z = \int \prod_j dz_j d\bar{z}_j dw_j d\bar{w}_j \delta(|z|^2 - 1) \delta(|w| - 1) e^{-S(z,w)}$$
 (5) {eq:toy\_Z}

In order to evaluate (5), we want to embed the space of fields  $\mathcal{F} = \mathbb{CP}^{N-1} \times \mathbb{CP}^{N-1}$  into a higher dimensional complex space such that

- 1. the new action  $\tilde{S}$  is holomorphic in the new variables (fields)
- 2. when we restrict to  $\mathcal{F}$ ,  $\tilde{S}$  reduces to S

We think of this embedding as an analytic continuation of the space of fields in an appropriate sense.

#### 1.2 Complexification of Real Analytic Manifolds

Let us first recall a basic construction of complexification of real analytic manifolds due to Bruhat and Whitney [1].

Let M be a real analytic manifold of dimension  $\dim_{\mathbb{R}} M = m$ . Moreover, let  $\{U_i, \phi_i\}$  be a real analytic atlas of M, with  $U_i \subset \mathbb{R}^m$  and charts  $\phi_i \colon U_i \to M$  so that the transition functions

$$\phi_{ij} = \phi_i^{-1} \circ \phi_i \colon U_{ij} \to U_{ij} \tag{6}$$

are real analytic diffeomorphisms. The idea of complexifying M is to find a complex manifold  $M^{\mathbb{C}}$  with  $\dim_{\mathbb{C}} M^{\mathbb{C}} = m$  and a (real analytic) isomorphism  $f \colon M \to \tilde{M} \subset M^{\mathbb{C}}$  of M onto a submanifold of  $M^{\mathbb{C}}$ . (Fancy way to say that M should be a real analytic submanifold of  $M^{\mathbb{C}}$  up to isomorphism) Now, find opens  $U_i^{\mathbb{C}} \subset \mathbb{C}^m$  such that  $U_i^{\mathbb{C}} \cap \mathbb{R}^m = U_i$  and extend the charts  $\phi_i$  charts  $\phi_i^{\mathbb{C}}$  such that

(i) the transition functions  $\phi_{ij}^{\mathbb{C}} \colon U_{ij}^{\mathbb{C}} \to U_{ij}^{\mathbb{C}}$  are biholomorphic

(ii) 
$$\phi_{ji}^{\mathbb{C}} = \left(\phi_{ij}^{\mathbb{C}}\right)^{-1}$$
 and  $\phi_{ii}^{\mathbb{C}} = id$ 

(iii) the transition functions  $\phi_{ij}^{\mathbb{C}}$  satisfy the usual 2-cocycle condition (gluing condition) on  $U_{ijk}^{\mathbb{C}}$ :  $\phi_{ij}^{\mathbb{C}} \circ \phi_{jk}^{\mathbb{C}} = \phi_{ik}^{\mathbb{C}}$ 

These conditions ensure that we can glue  $M^{\mathbb{C}}$  from the local data  $\{U_i^{\mathbb{C}}, \phi_i^{\mathbb{C}}\}$ :

$$M^{\mathbb{C}} = \coprod_{i} U_{i}^{\mathbb{C}} / \sim \quad , \quad z_{i} \sim z_{j} \text{ iff } z_{j} = \phi_{ji}^{\mathbb{C}}(z_{i}) \text{ on } U_{ij}^{\mathbb{C}}$$
 (7)

For more details on this construction see Cieliebak and Eliashberga's book [2]

#### 1.2.1 Example: The N-sphere

Consider the N-sphere  $S^N \subset \mathbb{R}^{N+1}$ . First, consider the following atlas: let  $p_{\pm} = (0, \dots, 0, \pm 1) \in S^N$  be the north and south pole respectively. We denote points on the sphere by  $x = (x_1, \dots, x_{N+1})$ ,  $||x||^2 = 1$  and points in  $\mathbb{R}^N$  by  $X = (X_1, \dots, X_N)$ . The atlas we consider is given by steoreographic projection through  $p_{\pm}$ : Let  $U_{\pm} = \mathbb{R}^N$  and  $V_{\pm} = S^N - \{p_{\pm}\}$ . Then define charts

$$\phi_{\pm} \colon U_{\pm} \to V_{\pm} \subset S^N \quad , \quad X \mapsto \left(\frac{2X}{1 + \|X\|^2}, \pm \frac{\|X\|^2 - 1}{\|X\|^2 + 1}\right)$$
 (8)

with inverse

$$\phi_{\pm}^{-1} \colon x \mapsto \left\{ \frac{x_i}{1 \mp x_{N+1}} \right\} \tag{9}$$

From this, one finds the transition functions

$$\phi_{+-} = (\phi_{-+})^{-1} = \phi_{-}^{-1} \circ \phi_{+} \colon X \mapsto \frac{X}{\|X\|^{2}}$$
(10)

**Remark 1.** There is a nice geometric interpretation of these transition functions. Note that the map

$$X \mapsto \frac{X}{\|X\|^2} \tag{11}$$

describes an involution at the unit sphere  $S^{N-1}$ . On the sphere, the maps differ merely by a sign switch in the  $x_{N+1}$  component and indeed, if one computes the transition functions directly on the embedded sphere (that is as maps from  $\mathbb{R}^{N+1} \to \mathbb{R}^{N+1}$ ) one finds

$$\phi_{+} \circ \phi_{-} \colon (x_i, x_{N+1}) \mapsto (x_i, -x_{N+1})$$
 (12)

which corresponds to a reflection of x about the equator! (It helps visualising this for the case 2-sphere) But under stereographic projection, a reflection about the equator becomes an inversion on the unit sphere  $S^{N-1}$  in  $\mathbb{R}^N$  (again, it helps working this out in the case N=2).

Now, since  $U_{\pm} = \mathbb{R}^N$  there exist obvious candidates for a complexification, namely  $U_{\pm}^{\mathbb{C}} = \mathbb{C}^N$ . We thus promote every X to a complex variable Z = X + iY. Conversely, we can promote any  $x \in \mathbb{R}^{N+1}$  satisfying  $||x||^2 = \sum_i x_i^2 = 1$  to complex variables z satisfying

$$\sum_{j} z_{j}^{2} = 1 \tag{13} \qquad \text{(eq:toy_quadric)}$$

The above equation defines a hypersurface (so-called quadric) inside  $\mathbb{C}^{N+1}$ .

There is a very interesting observation I found in this stackexchange post: the quadric Q defined by (13) is diffeomorphic to the tangent space  $TS^N$ . The diffeomorphism is realised by the following map:

$$\Psi \colon TS^N \to Q$$
 ,  $(x,y) \mapsto z = \Psi(x,y) = x\sqrt{1 + ||y||^2} + iy$  (14)

with inverse

$$\Psi^{-1}(x+iy) = \left(\frac{x}{\sqrt{1+\|y\|^2}}, y\right)$$
 (15)

where  $||y||^2 = \sum_i y_i^2$ 

Remark 2. Verification that  $\Psi$  does indeed define a diffeomorphism goes by a straight forward calculation. (Recall in particular that the tangent space  $TS^N$  can be described by pairs  $(x,y) \in \mathbb{R}^{N+1}$  such that  $\langle x,y \rangle = \sum_i x_i y_i = 0$ )

There exists another very interesting diffeomorphism (which I have discovered in this stackexchange post

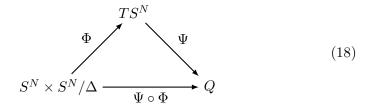

$$\Phi \colon S^N S^N / \Delta \to T S^N \quad , \quad (u,v) \mapsto \left( u, \frac{v - \langle u,v \rangle \, u}{1 - \langle u,v \rangle} \right) \tag{16} \quad \{ \texttt{eq:diff\_SNSN\_TSN} \}$$

Its inverse is given by

$$\Phi^{-1}: TS^N \to S^N \times S^N / \Delta$$
 ,  $(x,y) \mapsto \left(x, \frac{x(\|y\|^2 - 1) + 2y}{\|y\|^2 + 1}\right)$  (17)

**Remark 3.** The map (16) is the sterepgraphic projection of  $v \in S^N$  through the "pole"  $u \in S^N$ .

Finally we have the following commutative diagram

The idea is that we can use  $S^N \times S^N$  to parametrise Q nicely and that maybe the action of  $\mathrm{U}(1)$  on  $S^N$  can naturally be lifted to a diagonal action on  $S^N \times S^N$ . In fact, I believe that the  $\mathrm{U}(1)$  action on  $S^N$  leaves the norm in variant sp that the map  $\Psi \circ \Phi$  has a chance to be an equivariant map. However, this remains to be checked!
